2. Project Details

Project Title: Placement Portal Web Application

Problem Statement:

Many colleges and universities still manage placements manually, causing delays, errors, and inefficient communication between students, recruiters, and administrators. The objective is to create a **web-based platform** that streamlines the entire placement process.

Approach:

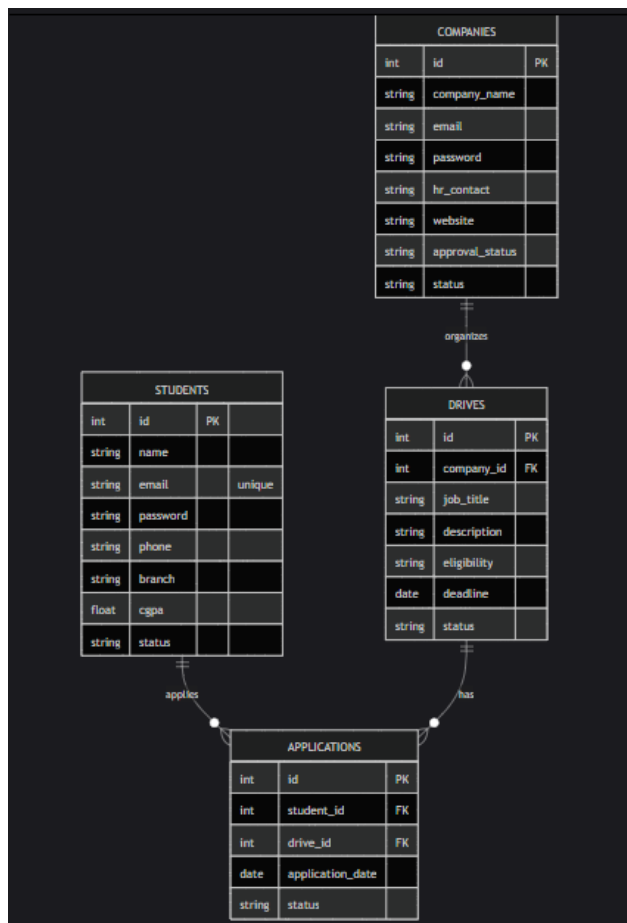

1. Developed a **role-based system** with Admin, Student, and Company dashboards.
2. Designed **database schema** for students, companies, drives, and applications.
3. Implemented **CRUD operations** for all entities.
4. Added features for **application tracking, shortlisting, approvals, and blacklisting**.
5. Used **Bootstrap + Jinja2** for frontend and **Flask + SQLite** for backend.
6. Created secure **login/registration** flows and session management.
7. Generated reports and statistics for Admin dashboard.

3. AI/LLM Declaration

This project was developed **without direct AI-generated coding assistance**. Any AI/LLM tools used were only for **research, documentation, or guidance purposes**, and all code implementation is authored by the students.

4. Frameworks and Libraries Used

- **Backend:** Flask (Python)
- **Frontend:** HTML, CSS, Bootstrap, Jinja2
- **Database:** SQLite
- **Python Libraries:** datetime, sqlite3, flask, werkzeug.security (optional for password hashing)

6. API Resource Endpoints (if any)

Even though this is a Flask web app, the backend routes act as endpoints:

Endpoint	Method	Description
/login	POST	User login for Admin/Student/Company
/register_student	POST	Student registration
/register_company	POST	Company registration
/student/dashboard	GET	Student view of approved drives
/apply/<drive_id>	GET	Apply for a drive
/company/create_drive	POST	Create new drive
/company/applications/<drive_id>	GET	View applications for a drive
/admin/approve_company/<id>	GET	Admin approves company
/admin/drives	GET	Admin views all drives
